## Bar Plots of Categorical Variables

According to the box plot for continuous variables:

- **Age**, **BMI**, and **SBP** appear reasonably normally distributed, with expected ranges for an adult population; **LDL cholesterol** and **time** since vaccination show a wider range and some outliers, which may impact linear models.
- **log\_antibody** (response) appears fairly symmetrical, which supports its use as a continuous response in linear or GAM models.
- Correlations and non-linear trends should be assessed in the next step to guide model form.

According to the bar plot for categorical variables:

- **Gender** is fairly balanced between Female and Male;
- **Race** is skewed, with a majority of participants identifying as White (Category 1). Other racial/ethnic groups are underrepresented;
- **Smoking** status shows that the majority are never smokers (Category 0), with fewer current and former smokers;
- A large proportion of participants do not have **diabetes**;
- A moderate split exists for **hypertension**, which may contribute meaningfully to clinical outcome variation
- Demographically, the population is balanced by gender but skewed by race and smoking status.

Overall, we believe the response variable **log\_antibody** is well-behaved, and further correlation analysis(eg. bivariate) is needed.

## Model Training
